Heterogeneous Impact of the Global Financial Cycle

Aleksei Oskolkov
University of Chicago, Department of Economics

October 19, 2023

motivation

In global downturns

- investors sell foreign assets (retrenchment)
- prices fall more in emerging markets
- outward flows fall more in advanced economies

evidence

This paper: a multiple-country model to study

- joint determination of gross capital flows and asset price responses
- heterogeneity in exposure to global shocks

model

Global intermediaries + multiple countries

Main experiment: shock to risk-bearing capacity of global intermediaries

- countries issue risky assets
- local agents and global intermediaries trade these assets
- intermediaries borrow from local agents

In equilibrium: heterogeneity in wealth, different exposure to foreign demand shocks

mechanism and key results

Intermediaries seek to sell risky assets in all countries

- rich countries: domestic investors absorb sales by foreigners
- poor countries: low wealth $\longrightarrow$ unable to replace foreign demand

Equilibrium implications:

- assets issued in rich countries appreciate $\longrightarrow$ good substitutes for safe assets
- rich countries insure poor ones
- wealth inequality between countries rises in downturns
- global intermediaries become relatively richer in downturns

explaining the data

Data: outward flows and risky assets prices procyclical in both AE and EM

Estimate that financial and real shocks positively correlated

- financial shocks induce countercyclical asset prices in AE
- real shocks (output) explain procyclicality

Correlation of wealth with global aggregates is 3 times lower in AE

- due to financial shocks

literature

Evidence of the global financial cycle and heterogeneous exposures:

- Miranda-Agrippino Rey 2020,2022, Miranda-Agrippino et al 2020, Barrot Serven 2018, Habib Venditti 2019, Cerutti et al 2019, Chari et al 2020, Eguren-Martin et al 2021, Gelos et al 2022, Kalemli-Ozkan 2019

This paper: analyze heterogeneity as an equilibrium feature in a model

Models of the global financial cycle and retrenchment:

This paper: explain heterogeneity using retrenchment, study risk-sharing

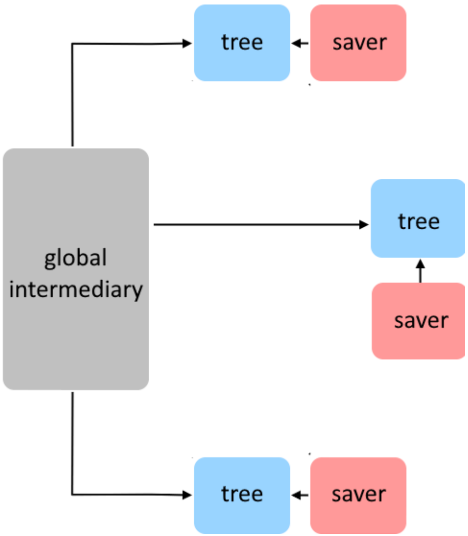
outline

— model

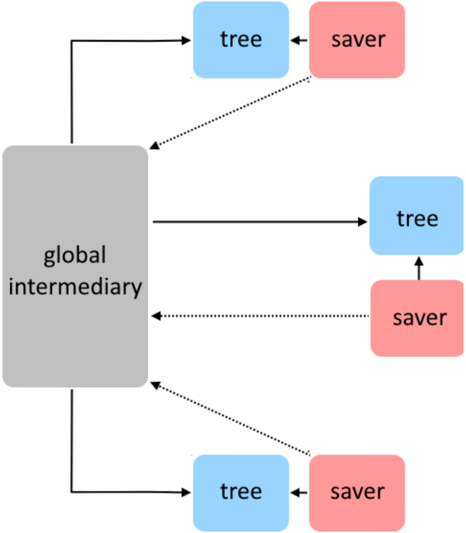
— shock to risk-taking capacity of global intermediaries

— quantitative evaluation and empirical evidence model

model map



model map



regular countries

Countries $i \in [0, 1]$

- Lucas tree with price p_{it}, fixed supply of 1
- cumulative yield up to t denoted by y_{it}
- flow yield $dy_{it} = \nu_t dt + \sigma dZ_{it}$

problem of local savers

$$\max_{\{c_{it},\theta_{it}\}_{t\geq 0}} \mathbb{E}\left[\rho \int_0^\infty e^{-\rho t} \ln(c_{it}) dt\right] \tag{1}$$

$$\text{s.t. } dw_{it} = (r_t w_{it} - c_{it})dt + \theta_{it} w_{it} dR_{it} \tag{2}$$

- share $1 - \theta_{it}$ to intermediary's debt, interest rate $r_t dt$
- allocate share θ_{it} to tree, excess returns dR_{it}

$$dR_{it} = \frac{1}{p_{it}}(dy_{it} + dp_{it}) - r_t dt \equiv \mu_{it}^R dt + \sigma_{it}^R dZ_{it} \tag{3}$$

- solution:

$$\theta_{it} = \frac{\mu_{it}^R}{(\sigma_{it}^R)^2} \tag{4}$$

intermediaries

Invest in trees in all countries, borrow from all savers

- assign portfolio weight $\hat{\theta}_{it}$ to country i
- issue debt m_t, pay interest $r_t dt$
- consume $\hat{c}_t$

$$d\hat{w}_t = \int_0^1 \hat{\theta}_{it}\hat{w}_t(dR_{it} + r_t dt)di - m_t r_t dt - \hat{c}_t dt \tag{5}$$

Limited risk-taking capacity: cannot fully diversify their portfolio:

- non-trivial portfolio in equilibrium
- time-varying capacity to take risk

intermediary's problem

VAR-type constraint bounds total amount of risk:

foundation

$$\int_0^1 \mathbb{V}_t[\hat{\theta}_{it} dR_{it}]di \leq \gamma_t \int_0^1 \mathbb{E}_t[\hat{\theta}_{it} dR_{it}]di \tag{6}$$

Portfolio and consumption choice

$$\max_{\{\hat{c}_t, m_t, f_t\}_{t\geq 0}} \mathbb{E}\left[\hat{\rho} \int_0^\infty e^{-\hat{\rho}t} \ln(\hat{c}_t) dt\right] \tag{7}$$

Cost parameter γ_t governs risk-taking capacity:

$$\hat{\theta}_{it} = \gamma_t \frac{\mu_{it}^R}{(\sigma_{it}^R)^2} \tag{8}$$

equilibrium

Prices $\{p_{it}\}$, interest rate r_t, wealth distribution, and $\{c_{it}, \hat{c}_t, \theta_{it}, \hat{\theta}_{it}, m_t\}$ such that markets clear:

$$1 = \frac{\hat{\theta}_{it}\hat{w}_t}{p_{it}} + \frac{\theta_{it} w_{it}}{p_{it}} \quad \text{all } i \in [0,1] \tag{9}$$

$$m_t = \int_0^1 w_{it}(1-\theta_{it})di \tag{10}$$

$$\nu_t = \hat{c}_t + \int_0^1 c_{it} di \tag{11}$$

equilibrium characterization

Solve for country-specific variables as functions of w and aggregate states

Prices only depend on $r(t)$ and a global factor $\varphi(t) = \gamma(t)\hat{w}(t)$

Time-varying risk premium:

$$\mu_R(w,t) = \sigma_R(w,t)^2 \cdot \frac{p(w,t)}{\varphi(t) + w} \tag{12}$$

shock to risk-taking capacity $\gamma(t)$

Impulse response to an unanticipated jump in $\gamma(t)$ for illustration:

$$\gamma(t) = \gamma - e^{-\mu_\gamma t}\Delta_\gamma \tag{13}$$

Immediate effect: hit global factor $\varphi(t) = \gamma(t)\hat{w}(t)$

- demand for risky assets falls
- interest rate falls

shock to $\gamma(t)$: prices

Changes in asset prices on impact can be decomposed into

- response to interest rate $r(t)$
- response to global factor $\varphi(t)$

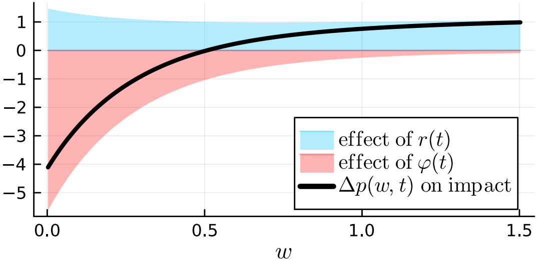


Figure: percentage changes in $p(w,t)$ on impact.

shock to $\gamma(t)$: holdings

Tree holdings of domestic agents $\theta(w, t)w$

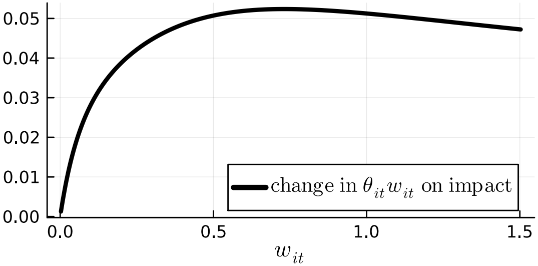

Figure: change in tree holdings on impact.

adding a portfolio constaint

Now suppose there is a constraint on portfolio allocation:

$$\theta_{it} \leq \overline{\theta} \tag{14}$$

Risky holdings cannot exceed $\overline{\theta} w_{it}$

Binds for poor countries with high returns and low wealth

time-varying risk premium

Excess returns depend on whether the constraint is binding

stochastic dynamics

- unconstrained countries:

$$\mu_R(w,t) = \sigma_R(w,t)^2 \cdot \frac{p(w,t)}{\varphi(t)+w} \tag{15}$$

- constrained countries:

$$\mu_R(w,t) = \sigma_R(w,t)^2 \cdot \frac{p(w,t)-\overline{\theta}w}{\varphi(t)} \tag{16}$$

inelastic markets

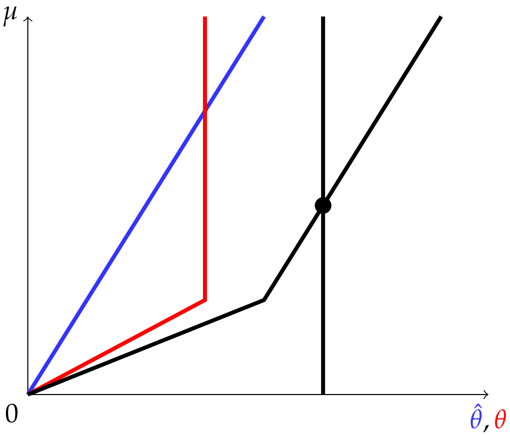

Figure: Supply is vertical. Demand $\hat{\theta}$ from global banks in blue, from local savers θ in red.

inelastic markets

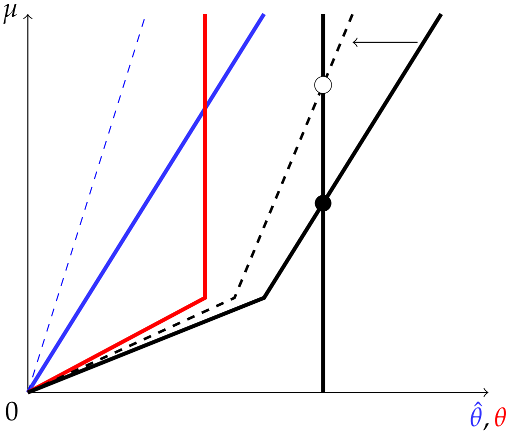

Figure: Supply is vertical. Demand $\hat{\theta}$ from global banks in blue, from local savers θ in red.

elastic markets

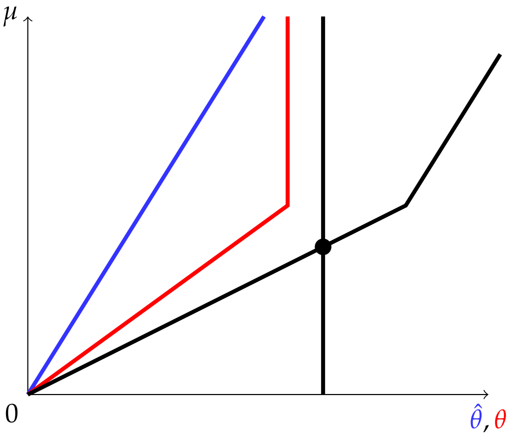

Figure: Supply is vertical. Demand $\hat{\theta}$ from global banks in blue, from local savers θ in red.

elastic markets

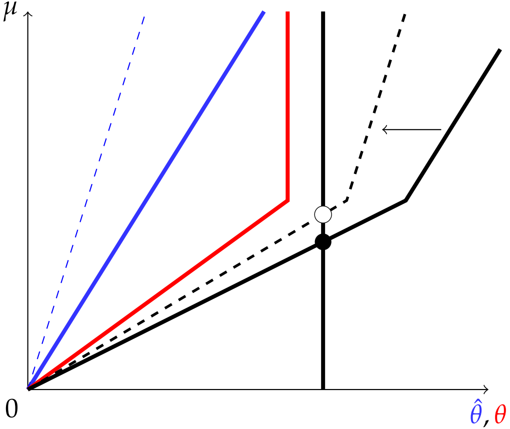

Figure: Supply is vertical. Demand $\hat{\theta}$ from global banks in blue, from local savers θ in red.

adding US assets

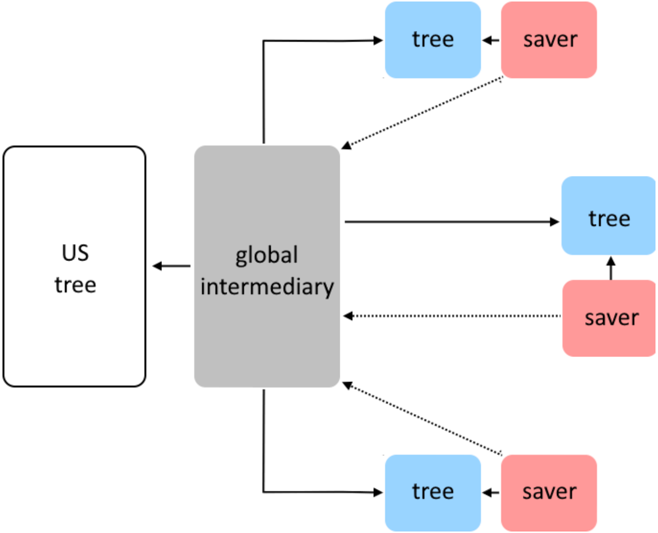
Lucas tree in the dominant country, fixed supply q, held by intermediaries

Price of tree $\hat{p}_t$, pays $\nu_t dt$:

$$d\hat{R}_t = \frac{1}{\hat{p}_t}(d\hat{p}_t + \nu_t dt) - r_t dt \tag{17}$$

No risk in dividends, no associated ambiguity

adding US assets



solving for prices

Expressions for risk premium turn into non-linear PDE for prices $p(w,t)$ equations

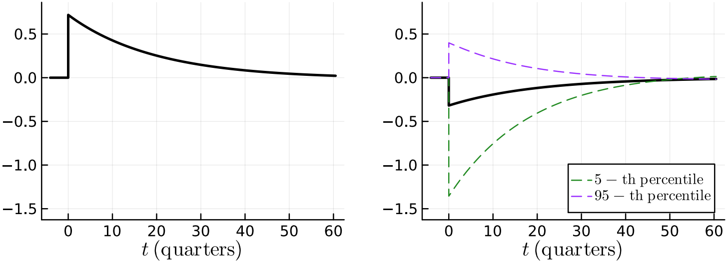
- use definition of returns to turn equilibrium conditions into PDE for prices
- PDE has unknown coefficients (μ^p, σ^p)
- use Itô's lemma to characterize (μ^p, σ^p) in terms of (μ^w, σ^w)
- use budget constraints to get (μ^w, σ^w)

At the end: asset prices $p(w,t)$ and wealth density $g(w,t)$ that solved a coupled system shock to risk-taking capacity

shock to $\gamma(t)$: prices

- safe asset price $\hat{p}(t)$ increases on impact
- risky asset prices $p(w,t)$ move in different directions

quantities



(a) percentage change in $\hat{p}(t)$ (b) percentage change in $p(w,t)$

shock to $\gamma(t)$: holdings

Tree holdings $h(w,t)$ defined as

$$h(w,t) = \frac{\theta(w,t)w}{p(w,t)} \tag{18}$$

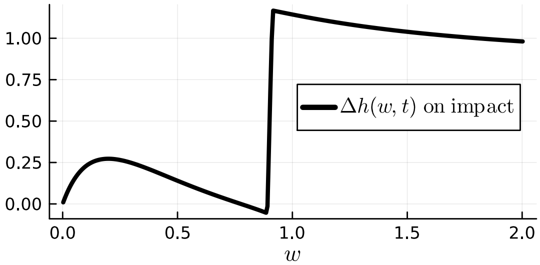


Figure: change in tree holdings on impact.

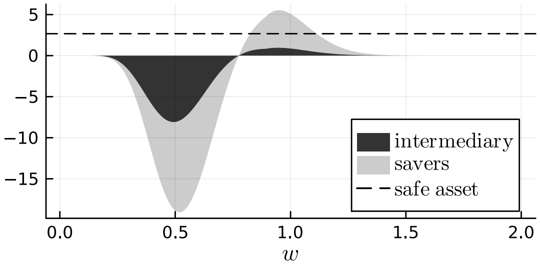
shock to $\gamma(t)$: loss-sharing

Figure: gains and losses on impact in percent of global GDP, weighted by density



- insurance: AE $\rightarrow$ intermediary $\rightarrow$ EM
- AE and intermediary become **richer**, EM become **poorer**

macro adjustment | excess returns

calibration and estimation

calibration

Calibrate steady state to reproduce aggregates, moments of assets/liabilities ratio:

	model	target	source
aggregates:			
US wealth share	31.5%	32.3%	Credit Suisse 2022
US output share	23.7%	22.8%	World Bank
average risk premium	2.62pp	2.5pp	Gourinchas Rey 2022
emerging market premium	2.22pp	2.3pp	Adler Garcia-Macia 2018
external assets to external liabilities:			
mean	1.071	1.075	IFS (IMF)
standard deviation	0.686	0.685	IFS (IMF)
q25	0.614	0.621	IFS (IMF)
q50	0.849	0.877	IFS (IMF)
q75	1.285	1.249	IFS (IMF)

parameter values

estimation

Estimate parameters of aggregate shocks: $(\mu_\gamma, \mu_\nu, \sigma_\gamma, \sigma_\nu)$

Simulate the model, compute moments of first-order deviations $\tilde{m}(t)$ and $\tilde{p}(t)$

- total external assets

$$m(t) = \int w(1 - \theta(w,t))dG(w,t) \tag{19}$$

- average risky asset price

$$p(t) = \int p(w,t)dG(w,t) \tag{20}$$

moments

Data: quarterly returns on MSCI ex-US index for $\tilde{p}_t$, total outflows from IMF data for $\tilde{m}_t$

Table: targets

	$\text{std}(\tilde{p}_t)$	$\text{std}(\tilde{m}_t)$	$\text{corr}(\tilde{p}_t, \tilde{m}_t)$	$\text{corr}(\tilde{p}_t, \tilde{p}_{t-1})$	$\text{corr}(\tilde{m}_t, \tilde{m}_{t-1})$
data	0.048	0.049	0.738	0.785	0.828
model	0.048	0.049	0.740	0.779	0.839

estimated parameters

untargeted moments

Associate AE to unconstrained countries

inpulse responses

Gross outflows relative to assets are more volatile in AE:

	$\text{std}(\tilde{m}_t^{AE})$	$\text{std}(\tilde{m}_t^{EM})$
data	0.045	0.035
model	0.074	0.027

Asset prices are less volatile in AE:

	$\text{std}(\tilde{p}_t^{AE})$	$\text{std}(\tilde{p}_t^{EM})$
data	0.042	0.059
model	0.030	0.048

untargeted moments: cyclicality

- cyclicality of outflows stronger in AE
- cyclicality of prices is stronger in EM
- relative performance negatively correlated with relative outflows

	$\text{corr}(\tilde{m}_t^{AE} - \tilde{m}_t^{EM}, \tilde{m}_t)$	$\text{corr}(\tilde{p}_t^{AE} - \tilde{p}_t^{EM}, \tilde{m}_t)$	$\text{corr}(\tilde{p}_t^{AE} - \tilde{p}_t^{EM}, \tilde{m}_t^{AE} - \tilde{m}_t^{EM})$
data	0.67	-0.16	-0.17
model	0.13	-0.55	-0.59

output shocks

shock to output in ROW and US

EIS = 1: shocks to $\gamma(t)$ do not destroy wealth, no swings in aggregate consumption:

$$\rho \int_0^1 w dG(w,t) + \hat{\rho}\hat{w}(t) = \nu(t)(1+q) \tag{21}$$

Isolated shock to $\gamma(t)$ necessarily redistributive

Data: prices go up and down together

shocks to $\nu(t)$

Interest rate rises, all prices fall

Poor countries more exposed to foregin demand $\hat{w}(t) \longrightarrow$ prices fall more prices

Loss distribution very similar for shocks to $\nu(t)$ in ROW and US losses

variance decomposition

	full model	only γ	only ν
m_t	0.049	0.024	0.044

relative performance			
$p_t^{AE} - p_t^{EM}$	-0.55	-0.95	-0.18

Table: correlations of first-order responses with total outflows $\tilde{m}_t$

cyclicality of wealth

Shocks to γ generate countercyclical wealth dynamics in AE, procyclical in EM

	full model	only γ	only ν
wealth			
$\hat{w}_t$	0.30	-0.95	0.11
w_t^{AE}	0.32	-0.89	0.97
w_t^{EM}	0.94	0.97	0.99

Table: Correlations of wealth with total outflows $\tilde{m}_t$

conclusion

Domestic demand in richer countries is more elastic due to size and portfolio constraints

- sudden stops lead to retrenchment that stabilizes prices
- assets issued by richer countries are endogenously safer
- wealth transfers: rich $\rightarrow$ dominant $\rightarrow$ poor
- wealth redistribution: regressive

Thank you for your attention

outflows in AE and EM

- net acquisition of foreign assets (flows): f_{it}
- principal component F_t
- total foreign assets (stock) A_{it}
- position-adjusted flows: $m_{it} = f_{it} / A_{i,t-1}$

Table: dependent variables expressed as percentage

	m_t^{AE}	m_t^{EM}	$m_t^{AE} - m_t^{EM}$
F_t	3.87	1.44	**2.43**

back

intermediary's problem (ambiguity)

Consider misspecified processes $d\hat{Z}_{it} = dZ_{it} + \xi_{it} dt$ for idiosyncratic shocks:

$$dR_{it} = (\mu^R_{it} - \xi_{it}\sigma^R_{it})dt + \sigma^R_{it} d\hat{Z}_{it} \tag{29}$$

Minmax problem: first choose corrections ξ_t, then portfolio and consumption

$$\max_{\{\hat{c}_t, m_t, f_t\}_{t\geq 0}} \min_{\{\xi_t\}_{t\geq 0}} \mathbb{E} \int_0^\infty e^{-\hat{\rho} t} \left(\hat{\rho} \ln(\hat{c}_t) + \frac{\gamma_t}{2} \int_0^1 \xi^2_{it} di \right) dt \tag{30}$$

Cost parameter γ_t governs risk-taking capacity:

back

$$\hat{\theta}_{it} = \gamma_t \frac{\mu^R_{it}}{(\sigma^R_{it})^2} \tag{31}$$

premium for aggregate risk

Intermediaries take the following positions: back

$$\hat{\theta}_{it} = \gamma_t \frac{\mu_{it}^R - \tilde{\sigma}_{it}^R x_t}{(\sigma_{it}^R)^2} \tag{32}$$

Here the aggregate risk premium x_t is

$$x_t = \frac{\gamma_t \int_0^1 \frac{\mu_{it}^R \tilde{\sigma}_{it}^R}{(\sigma_{it}^R)^2} di}{1 + \gamma_t \int_0^1 \frac{(\tilde{\sigma}_{it}^R)^2}{(\sigma_{it}^R)^2} di} \tag{33}$$

intermediaries with a VAR constraint

Issue short-term riskless liabilities m_t, invest $(\hat{\theta}_{it})_i$ in regular country trees:

$$d\hat{w}_t = \int_0^1 \hat{\theta}_{it}\hat{w}_t(dR_{it} + r_t dt)di - m_t r_t dt - \hat{c}_t dt \tag{34}$$

$$\int_0^1 \hat{\theta}_{it}\hat{w}_t di = \hat{w}_t + m_t \tag{35}$$

$$\int_0^1 \mathbb{V}_t[\hat{\theta}_{it}(dR_{it} - \tilde{\sigma}_{it}^R \cdot dW_t)]di \leq \gamma_t \int_0^1 \mathbb{E}_t[\hat{\theta}_{it}(dR_{it} - \tilde{\sigma}_{it}^R x_t)]di \tag{36}$$

Net worth $\hat{w}_t$, consumption rate $\hat{c}_t$, log utility

Result: constant consumption rate $\hat{c}_t = \hat{\rho}\hat{w}_t$ and

back

$$\hat{\theta}_{it} = \gamma_t \frac{\mu_{it}^R - \tilde{\sigma}_{it}^R x_t}{(\sigma_{it}^R)^2} \tag{37}$$

equilibrium with aggregate shocks

Given the process for excess returns

$$dR(w,\mathcal{S}) = \mu_R(w,\mathcal{S})dt + \sigma_R(w,\mathcal{S})dZ + \tilde{\sigma}_R(w,\mathcal{S}) \cdot dW \tag{38}$$

In equilibrium, excess returns satisfy

back

$$\mu_R(w,\mathcal{S}) = x(\mathcal{S}) \cdot \tilde{\sigma}_R(w,\mathcal{S}) + \tag{39}$$
$$\sigma_R(w,\mathcal{S})^2 \cdot \max\left\{ \frac{p(w,\mathcal{S})(\sigma_R(w,\mathcal{S})^2 + |\tilde{\sigma}_R(w,\mathcal{S})|^2) - wx(\mathcal{S}) \cdot \tilde{\sigma}_R(w,\mathcal{S})}{\varphi(\mathcal{S})(\sigma_R(w,\mathcal{S})^2 + |\tilde{\sigma}_R(w,\mathcal{S})|^2) + w\sigma_R(w,\mathcal{S})^2}, \frac{p(w,\mathcal{S}) - \overline{\theta}w}{\varphi(\mathcal{S})} \right\}$$

Here $x(\mathcal{S})$ is the aggregate risk premium

$$x(\mathcal{S}) = \frac{\gamma \int \frac{\mu_R(w,\mathcal{S})\tilde{\sigma}_R(w,\mathcal{S})}{(\sigma_R(w,\mathcal{S}))^2} dG(w,\mathcal{S})}{1 + \gamma \int \frac{|\tilde{\sigma}_R(w,\mathcal{S})|^2}{(\sigma_R(w,\mathcal{S}))^2} dG(w,\mathcal{S})} \tag{40}$$

solving for prices and distributions

Shut down aggregate shocks, $\sigma_\gamma = \sigma_\nu = (0, 0)$ back

Given initial conditions, prices $p(w,t)$ and density $g(w,t)$ solve

$$r(t)p(w,t) - \partial_t p(w,t) = y(w,t) + \mu_w(w,t)\partial_w p(w,t) + \frac{1}{2}\sigma_w(w,t)^2\partial_{ww}p(w,t) \tag{41}$$

$$\partial_t g(w,t) = -\partial_w[\mu_w(w,t)g(w,t)] + \frac{1}{2}\partial_{ww}[\sigma_w(w,t)^2 p(w,t)] \tag{42}$$

Risk-adjusted payoff $y(w,t)$:

$$y(w,t) = \nu(t) - \left(\frac{\sigma}{1-\epsilon(w,t)\theta(w,t)}\right)^2 \max\left\{\frac{1}{w+\varphi(t)}, \frac{1}{\varphi(t)}\left(1 - \frac{\bar{\theta}w}{p(w,t)}\right)\right\} \tag{43}$$

with wealth elasticity of price $\epsilon(w,t) = w/p(w,t) \cdot \partial_w p(w,t)$

estimation results

Estimate 5 parameters: persistence (μ_γ, μ_ν) and loadings $(\sigma_{\gamma 1}, \sigma_{\gamma 2}, \sigma_{\nu 2})$

$$\begin{pmatrix} d\gamma_t \\ d\nu_t \end{pmatrix} = \begin{pmatrix} \mu_\gamma & 0 \\ 0 & \mu_\nu \end{pmatrix} \begin{pmatrix} \overline{\gamma} - \gamma_t \\ \overline{\nu} - \nu_t \end{pmatrix} dt + \begin{pmatrix} \sigma_{\gamma 1} & \sigma_{\gamma 2} \\ 0 & \sigma_{\nu 2} \end{pmatrix} \begin{pmatrix} dW_1 \\ dW_2 \end{pmatrix} \tag{44}$$

Results:

μ_γ	μ_ν	$\sigma_{\gamma 1}$	$\sigma_{\gamma 2}$	$\sigma_{\nu 2}$
0.2445	0.7757	-0.1258	-0.0843	-0.0039
(0.0450)	(0.0356)	(0.0098)	(0.0056)	(0.00006)

back

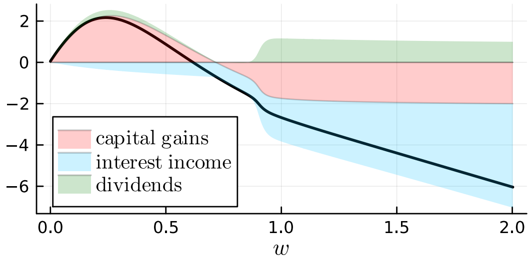
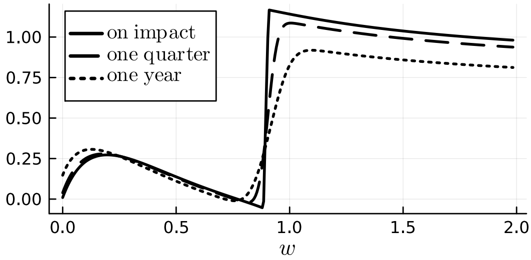
shock to $\gamma(t)$: adjustment

(a) Net income components.



(b) Domestic asset holdings.



- rich countries sell trees back to finance consumption and accumulate savings US adjustment back

US adjustment

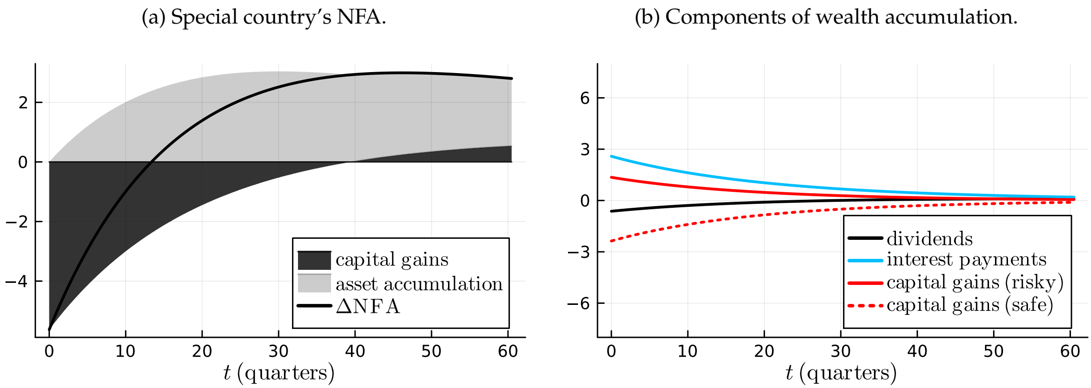


Figure: Responses of the special country's NFA and components of net income, percent of GDP.

back

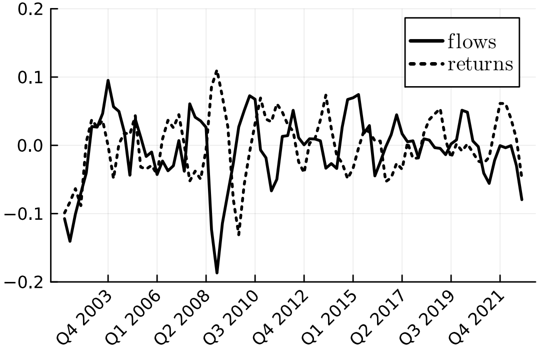
evidence on prices and flows

AE and EM separately

Model: relative performance of AE vs EM

- negatively correlated with aggregate outflows
- negatively correlated with Δ = AE outflows - EM outflows

Figure: returns $R_t^{AE} - R_t^{EM}$ and flows $\overline{f}_t^{AE} - \overline{f}_t^{EM}$



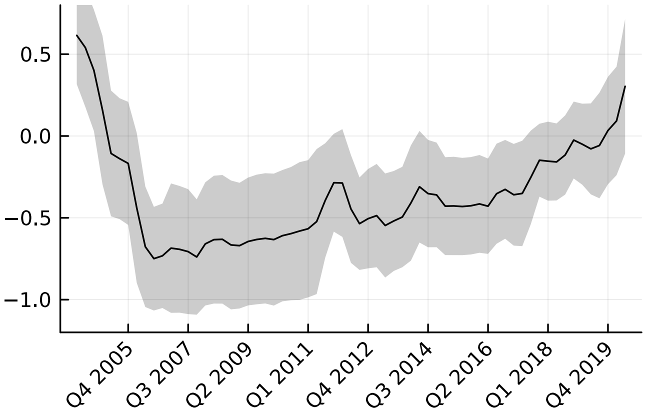
Define R_t as returns on MSCI for AE and EM

Table: pairwise correlations

	$\overline{f}_t^{AE} - \overline{f}_t^{EM}$	$R_t^{AE} - R_t^{EM}$
F_t	0.53	-0.28
$\overline{f}_t^{AE} - \overline{f}_t^{EM}$		-0.13

relative performance over time

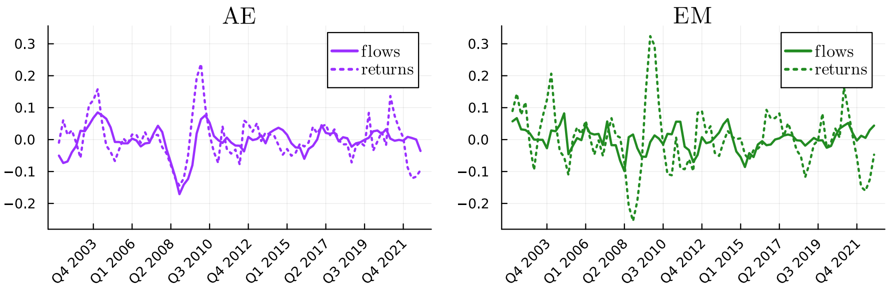
Figure: 5-year rolling-window correlation between $\overline{a}_t^{AE} - \overline{a}_t^{EM}$ and $R_t^{AE} - R_t^{EM}$



AE and EM separately

evidence: AE and EM separately

Figure: R_t^{AE} and $\bar{a}_t^{AE}$ on the left, R_t^{EM} and $\bar{a}_t^{EM}$ on the right

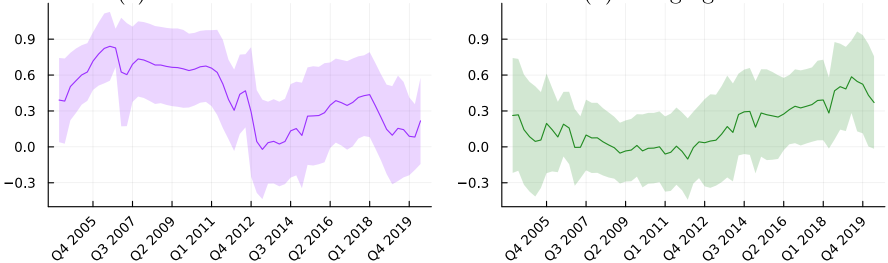


back

evidence: AE and EM separately

Figure: R_t^{AE} and $\bar{a}_t^{AE}$ on the left, R_t^{EM} and $\bar{a}_t^{EM}$ on the right

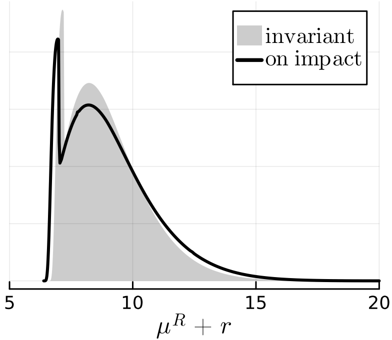
(a) advanced economies (b) emerging markets



back

distribution of required returns

Figure: required excess returns. back



output shocks: price responses

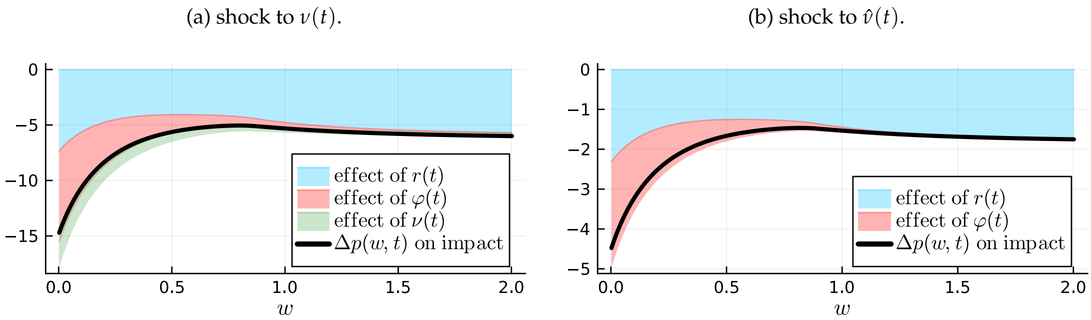


Figure: cross-section of the changes in risky asset prices on impact.

- interest rate rises, asset prices fall everywhere $\rightarrow$ wealth and consumption fall
- prices react to both $r(t)$ and $\varphi(t)$ in EM, only react to $r(t)$ in AE

back

output shocks: distribution of losses

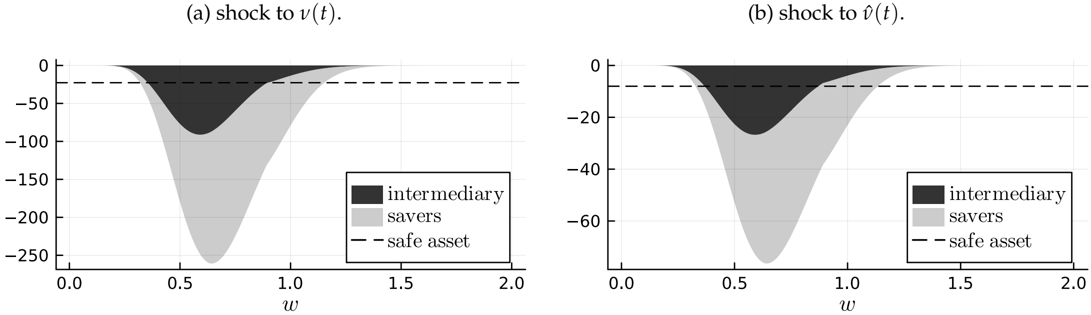

Figure: gains and losses on impact in percent of global GDP, weighted by density.

- loss distributions very similar for shocks of US and ROW origin
